Abstract
Blunt traumatic rupture of the diaphragm is a serious injury that is often difficult to diagnose. [1]
Diaphragmatic injuries were described first by Sennerus in 1541. Riolffi performed the first successful repair in 1886.
In 1951, Carter published the first case series, was this injury well understood and delineated. [2]
Approximately 0.8%-1.6% of patients with blunt trauma show a rupture in the diaphragm. (3) Blunt trauma accounts for 75% of ruptures and penetrating trauma accounts for the rest. Approximately 69% of hernias are left-sided, 24% are right-sided, and 15% are bilateral. [3]
The occult diaphragmatic injury was uncovered in a patient who has blunt chest trauma, after penetrating trauma. Diaphragmatic injury can be a difficult diagnosis in the setting of trauma and a significant number of injuries are missed on the initial presentation. We will be reporting a 56-year-old female who was admitted to our hospital with a history of cough, pain in the left chest as well as breathlessness of five days duration. She had a history of blunt trauma caused by an accidental gunshot in 1987…

Keywords: blunt Trauma, diaphragmatic injury, chest trauma

Background
Traumatic injury to diaphragm is an uncommon condition associated with severe blunt trauma which is usually missed in the early presentation to emergency. [1] The initial diagnosis of a blunt traumatic injury to the diaphragm is generally difficult because the early clinical and radiological findings are not clear. In acute circumstances, it is usually found on the table during exploratory laparotomy, although even then it may be missed. Nearly half of the patients remain asymptomatic and present with complications of the diseases several years after the onset of initial trauma.

In developing countries, where initial care of severely injured patients and diagnostic facilities are less than optimal, blunt traumatic diaphragmatic rupture may go undiagnosed. High index of clinical suspicion is required because of the missed diagnosis and potential for delayed presentation. We report a case of delayed presentation of post traumatic diaphragmatic hernia and reviewed the literature to highlight challenges in diagnosis and management of such cases. [3]

Case Report
A 56-year-old female was admitted in our hospital with a history of cough, pain in left chest as well as breathlessness of five days duration.

She had a history of a blunt trauma caused by accidental gunshot in 1987. She was transferred to the regional hospital where the patient underwent the removal of the bullet from the left axilla. The patient was then treated conservatively and no diaphragmatic hernia was detected. The chest X-ray showed a moderate air-fluid level in the left thoracic cavity. CT scan revealed a posterior defect on the left diaphragm with herniation of great omentum in thoracic cavity, as shown in Fig.1.

Case Report

presentation of post traumatic diaphragmatic hernia and reviewed the literature to highlight challenges in required because of the missed diagnosis and potential for delayed presentation. We report a case of delayed missed. Nearly half of the patients remain asymptomatic and present with complications of the diseases several.

Traumatic injury to diaphragm is an uncommon condition associated with severe blunt trauma which is usually conservatively and no diaphragmatic hernia was detected. The chest X-ray showed a moderate air-fluid level hospital where the patient underwent the removal of the bullet from the left axilla. The patient was then treated

Background

between 0.9 and 1.8 percent of the patients admitted to the autopsy in 1579. Antemortem diagnosis of traumatic DH is often missed if it occurs after seemingly innocuous injury or has a delayed presentation. Diagnosis should be reached as early as possible to reduce mortality. To make radiological diagnosis, radiologists should be familiar with a variety of imaging presentations of injury and maintain a high index of suspicion.

Discussion

The traumatic DH was apparently reported by Sennertus in 1541. Ambroise Pare described the first case of DH at autopsy in 1579. Antemortem diagnosis of traumatic DH was first made by Bowditch in 1853 and the first successful repair was done by Riolfi in 1886. [1]

The reported incidence of diaphragmatic rupture is between 0.9 and 1.8 percent of the patients admitted to the hospital with blunt trauma. [2]

The incidence rises up to 15% among patients with

Figure 1 The great omentum in the thoracic cavity (sagittal view)

The patient underwent left posterolateral thoracotomy and reduction of herniated great omentum into abdominal cavity first, and then the defect of diaphragm was repaired with single layer non absorbable suture. Her postoperative recovery was uneventful and she left the hospital after five postoperative days.

Figure 2. Diaphragmatic hernia (coronal view)

Traumatic DH is often missed if it occurs after seemingly innocuous injury or has a delayed presentation. Diagnosis should be reached as early as possible to reduce mortality.

To make radiological diagnosis, radiologists should be familiar with a variety of imaging presentations of injury and maintain a high index of suspicion.

In a clinically suspected case, if the chest X-ray is noncontributory, further imaging should be advised.

Open surgery or endoscopic surgery should be performed immediately to diagnose and treat the injury.

Conclusion

Figure 5. Surgical repair with single layer non absorbable suture

Thoracotomy (if required, extended into a thoracoabdominal incision) is advised in the patients with delayed presentation since the adhesions within the chest can be freed easily and reduction and repair of hernia will be easily accomplished.
